#### USPAS Accelerator Physics 2013 Duke University

#### Introductions, Relativity, E&M, Accelerator Overview

Todd Satogata (Jefferson Lab) / <u>satogata@jlab.org</u> Waldo MacKay (BNL, retired) / <u>waldo@bnl.gov</u> Timofey Zolkin (FNAL/Chicago) / t.v.zolkin@gmail.com <u>http://www.toddsatogata.net/2013-USPAS</u>

lefferson Lab

#### **Introductions and Outline**

- A sign-in sheet is being passed around
  - Please include any requests you have, e.g. topics you've heard about or that particularly interest you
- Introductions: Getting to know you, and us...
- Let's get it started

efferson Lab

- Course administrivia
- Relativistic mechanics review
- Relativistic E&M review, Cyclotrons
- Survey of accelerators and accelerator concepts

#### Syllabus I

Day	Topic	Who	Lab?
Mon AM	Intro, Relativity, Luminosity	Todd	
Mon PM	Weak Focusing, Stability Conditions	Waldo	
Tue AM	Weak Focusing, Hamiltonians	Waldo	(X)
Tue PM	Magnets and Field Expansions	Todd	
Wed AM	Strong Focusing Theory I	Waldo	
Wed PM	Strong Focusing Theory II	Waldo	
Thu AM	Lattice Exercises I	Todd	Yes
Thu PM	Lattice Exercises II	Waldo	
Fri AM	Lattice Design I	Todd	Yes
Fri PM	Lattice Design II	Todd	

- First week: Mostly transverse linear optics
  - Fundamentals and equations of motion
  - Magnet design, fields, descriptions
  - Linear transverse optics

Jefferson Lab

Magnetic lattices and lattice design

# Syllabus II

Day	Topic	Who	Lab?
Mon AM	Longitudinal Motion (Synchrotron)	Waldo	
Mon PM	Longitudinal Motion (Linac)	Todd	
Tue AM	Synchrotron Radiation	Waldo	Yes
Tue PM	Synchrotron Light Facility Lattices	Todd	
Wed AM	Resonances and Nonlinear Dynamics I	Waldo	
Wed PM	Nonlinear Dynamics II	Todd	
Thu AM	Space Charge and Beam-Beam	Todd	Yes (Exam)
Thu PM	Measurement Methods	Todd	
Fri AM	Polarization and Spin Dynamics	Waldo	

- Second week: Everything else ③
  - Longitudinal dynamics

Jefferson Lab

- Synchrotron radiation and cooling
- Nonlinear dynamics and collective effects
- Measurements and instrumentation

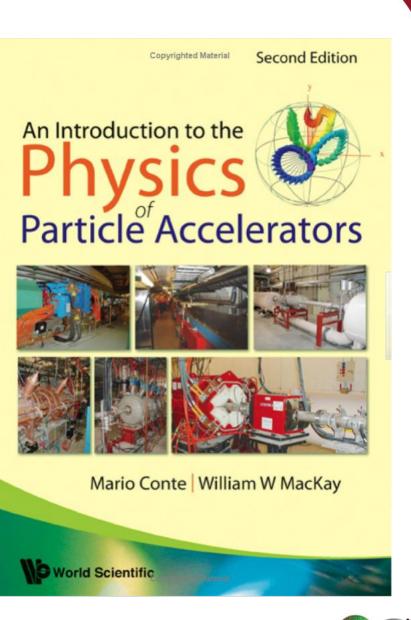

# Text

- Conte and MacKay
  - 2<sup>nd</sup> edition

Jefferson Lab

- We will cover quite a bit of this text
- You have the advantage of being able to nag one of the authors about its contents

## **Homework and Schedule**

- Homework is nearly half your grade!! (40%)
  - Tim is grading be nice to him ③

efferson Lab

- Collected at start of every morning class
- Tim's homework is to get it back to you the next day
- Lectures/lab times will run 09:00-12:00, 13:30-16:30(ish)
- Collaboration is encouraged! (Except on the final)
  - In fact, it's a good part of the reason why you're here!
  - Waldo and I will be available to work with you most evenings
- Cite references, contributions of teammates, etc
  - But everyone must hand in individual copies of homework

## **Relativity Review**

- Accelerators: applied special relativity
- Relativistic parameters:

Jefferson Lab

$$\beta \equiv rac{v}{c}$$
  $\gamma \equiv rac{1}{\sqrt{1-\beta^2}}$   $\beta = \sqrt{1-1/\gamma^2}$ 

- Later β and γ will also be used for other quantities, but the context should usually make them clear
- $\gamma = 1$  (classical mechanics) to  $\sim 2.05 \times 10^5$  (to date) (where??)
- Total energy U, momentum p, and kinetic energy W

$$U = \gamma mc^2$$
  $p = (\beta \gamma)mc = \beta \left(\frac{U}{c}\right)$   $W = (\gamma - 1)mc^2$ 

#### **Relative Relativity**

LEP energy

Input interpretation:

LEP (Large Electron Positron Collider) ce

Result:

208 GeV (gigaelectronvolts)

Unit conversions:

Jefferson Lab

0.208 TeV (teraelectronvolts)

 $2.08 \times 10^{11} \text{ eV} \text{ (electronvolts)}$ 

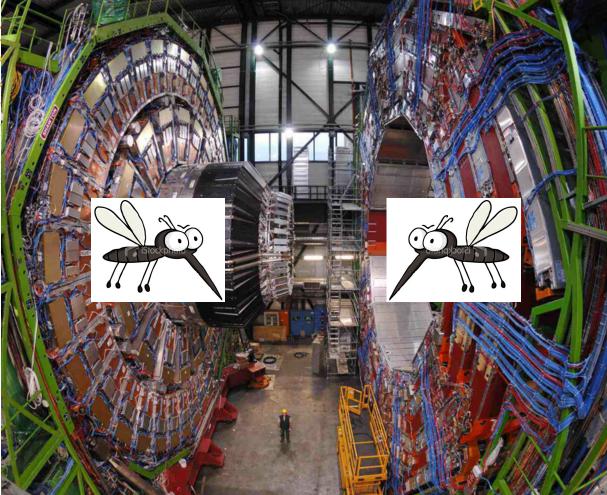

0.03333 µJ (microjoules)

 $3.333\times 10^{-8}~J~(\text{joules})$ 

0.3333 ergs

Comparisons as energy:

≈ ( 0.21 ≈ 1/5 ) ×

#### approximate kinetic energy of a flying mosquito ( $\approx 1.6 \times 10^{-7}$ J)

 $\approx$  2.2  $\times\,mass-energy$  equivalent of a Z boson  $(\approx 1.5 \times 10^{-8}\,\text{J})$ 

# **Convenient Units**

 $1 \text{ eV} = (1.602 \times 10^{-19} \text{ C})(1 \text{ V}) = 1.602 \times 10^{-19} \text{ J}$  $1 \text{ MeV} = 1.602 \times 10^{-13} \text{ J}$  $1 \text{ GeV} = 1.602 \times 10^{-10} \text{ J}$ 

- How much is a TeV?
  - Energy to raise 1g about 16 μm against gravity
  - Energy to power 100W light bulb 1.6 ns
- But many accelerators have 10<sup>10-12</sup> particles
  - Single bunch "instantaneous power" of tens of **Terawatts**
- Highest energy cosmic ray

efferson Lab

~300 EeV (3x10<sup>20</sup> eV or 3x10<sup>8</sup> TeV!) OMG particle
 Total

# **Relativity Review (Again)**

- Accelerators: applied special relativity
- Relativistic parameters:

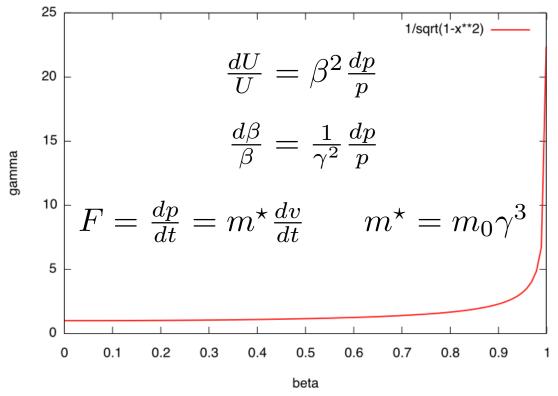

Jefferson Lab

$$\beta \equiv \frac{v}{c} \qquad \gamma \equiv \frac{1}{\sqrt{1 - \beta^2}} \qquad \beta = \sqrt{1 - 1/\gamma^2}$$

- Later β and γ will also be used for other quantities, but the context should usually make them clear
- $\gamma = 1$  (classical mechanics) to  $\sim 2.05 \times 10^5$  (oh yeah, at LEP)
- Total energy U, momentum p, and kinetic energy W

$$U = \gamma mc^2$$
  $p = (\beta \gamma)mc = \beta \left(\frac{U}{c}\right)$   $W = (\gamma - 1)mc^2$ 

# **Convenient Relativity Relations**

- All derived in the text, hold for all γ
- In "ultra" relativistic limit β≈1

Jefferson Lab

- Usually must be careful below γ≈5 or U≈5 mc<sup>2</sup>
- Many accelerator physics phenomena scale with γ<sup>k</sup> or (βγ)<sup>k</sup>

## (Frames and Lorentz Transformations)

- The lab frame will dominate most of our discussions
  - But not always (synchrotron radiation, space charge...)
- Invariance of space-time interval (Minkowski)

$$(ct')^2 - x'^2 - y'^2 - z'^2 = (ct)^2 - x^2 - y^2 - z^2$$

- Lorentz transformation of four-vectors
  - For example, time/space coordinates in z velocity boost

$$\begin{pmatrix} ct' \\ x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} \gamma & 0 & 0 & -\beta\gamma \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta\gamma & 0 & 0 & \gamma \end{pmatrix} \begin{pmatrix} ct \\ x \\ y \\ z \end{pmatrix}$$

letterson Lab

# (Four-Velocity and Four-Momentum)

- The proper time interval  $d\tau = dt/\gamma$  is Lorentz invariant
- So we can make a velocity 4-vector

$$cu^{\alpha} \equiv \left(\frac{dct}{d\tau}, \frac{dx}{d\tau}, \frac{dy}{d\tau}, \frac{dz}{d\tau}\right) = c\gamma(1, \beta_x, \beta_y, \beta_z)$$
  
Metric  $g^{\mu\nu} = g_{\mu\nu} = \text{diag}(1, -1, -1, -1)$ 

• We can also make a 4-momentum

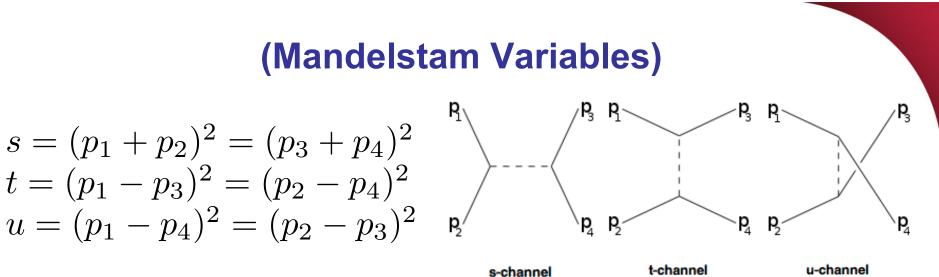

Jefferson Lab

$$p^{\alpha} \equiv mcu^{\alpha} = mc\gamma(1,\beta_x,\beta_y,\beta_z)$$

Double-check that Minkowski norms are invariant

$$u^{\alpha}u_{\alpha} = u^{\alpha}g_{\alpha\beta}u^{\beta} = \gamma^{2}(1-\beta^{2}) = 1$$
$$p^{\alpha}p_{\alpha} = m^{2}c^{2}u^{\alpha}u_{\alpha} = m^{2}c^{2}$$

$$s + t + u = (m_1^2 + m_2^2 + m_3^2 + m_4^2)c^2$$

- Lorentz-invariant two-body kinematic variables
  - p<sub>1-4</sub> are four-momenta

efferson Lab

- $\sqrt{s}$  is the total available center of mass energy
  - Often quoted for colliders
- Used in calculations of other two-body scattering processes
  - Moller scattering (e-e), Compton scattering (e- $\gamma$ )

# (Relativistic Newton)

$$\vec{F} = m\vec{a} = \frac{d\vec{p}}{dt}$$

 But now we can define a four-vector force in terms of four-momenta and proper time:

$$F^{\alpha} \equiv \frac{dp^{\alpha}}{d\tau}$$

 We are primarily concerned with electrodynamics so now we must make the classical electromagnetic Lorentz force obey Lorentz transformations

$$\vec{F} = q\left(\vec{E} + \vec{v} \times \vec{B}\right)$$

efferson Lab

#### **Relativistic Electromagnetism**

 Classical electromagnetic potentials can be shown to combine to a four-potential (with c=1):

$$A^{\alpha} \equiv (\Phi, \vec{A})$$

The field-strength tensor is related to the four-potential

$$F^{\alpha\beta} = \partial^{\alpha}A^{\beta} - \partial^{\beta}A^{\alpha} = \begin{pmatrix} 0 & E_{x} & E_{y} & E_{z} \\ -E_{x} & 0 & -B_{z} & B_{y} \\ -E_{y} & B_{z} & 0 & -B_{x} \\ -E_{z} & -B_{y} & B_{x} & 0 \end{pmatrix}$$

• E/B fields Lorentz transform with factors of  $\gamma$ , ( $\beta\gamma$ )

16

efferson Lab

**USPAS** Accelerator Physics

## (Lorentz Lie Group Generators)

 Lorentz transformations can be described by a Lie group where a general Lorentz transformation is

$$A = e^L \qquad \det A = e^{\operatorname{Tr} L} = +1$$

where L is 4x4, real, and traceless. With metric g, the matrix gL is also antisymmetric, so L has the general six-parameter form

$$L = \begin{pmatrix} 0 & L_{01} & L_{02} & L_{03} \\ L_{01} & 0 & L_{12} & L_{13} \\ L_{02} & -L_{12} & 0 & L_{23} \\ L_{03} & -L_{13} & -L_{23} & 0 \end{pmatrix}$$

**Deep** and **profound** connection to EM tensor  $\mathsf{F}^{\alpha\beta}$ 

efferson Lab

J.D. Jackson, Classical Electrodynamics 2<sup>nd</sup> Ed, Section 11.7

# **Relativistic Electromagnetism II**

The relativistic electromagnetic force equation becomes

$$\frac{dp^{\alpha}}{d\tau} = m\frac{du^{\alpha}}{d\tau} = \frac{q}{c}F^{\alpha\beta}u_{\beta}$$

Thankfully we can write this in somewhat simpler terms

$$\frac{d(\gamma m \vec{v})}{dt} = q \left( \vec{E} + \vec{v} \times \vec{B} \right)$$

- That is, "classical" E&M force equations hold if we treat the momentum as relativistic,  $\vec{p} = \gamma m \vec{v} = \gamma \vec{\beta} m c$
- If we dot in the velocity, we get energy transfer

lefferson Lab

$$\frac{d\gamma}{dt} = \frac{q\vec{E}\cdot\vec{v}}{mc^2}$$

 Unsurprisingly, we can only get energy changes from electric fields, not (conservative) magnetic fields

#### Constant Magnetic Field (Zero Electric Field)

 In a constant magnetic field, charged particles move in circular arcs of radius ρ with constant angular velocity ω:

$$\vec{F} = \frac{d}{dt}(\gamma m \vec{v}) = \gamma m \frac{d\vec{v}}{dt} = q\vec{v} \times \vec{B}$$

$$\vec{v} = \vec{\omega} \times \vec{\rho} \implies q\vec{v} \times \vec{B} = \gamma m\vec{\omega} \times \frac{a\rho}{dt} = \gamma m\vec{\omega} \times \vec{v}$$

• For  $\vec{B} \perp \vec{v}$  we then have

$$qvB = \frac{\gamma m v^2}{\rho} \qquad p = \gamma m(\beta c) = q(B\rho) \qquad \frac{p}{q} = (B\rho)$$
$$\omega = \frac{v}{\rho} = \frac{qB}{\gamma m}$$
  
From Lab T. Satogata / January 2013 USPAS Accelerator Physics 19

# **Rigidity: Bending Radius vs Momentum**

$$\frac{p}{q} = (B\rho)$$

Accelerator (magnets, geometry)

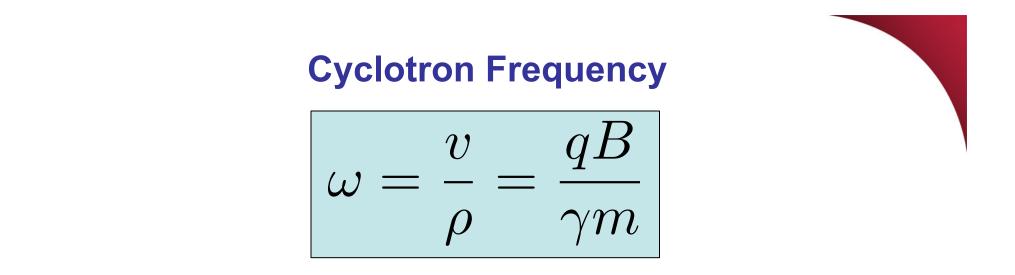

- This is such a useful expression in accelerator physics that it has its own name: rigidity
- Ratio of momentum to charge
  - How hard (or easy) is a particle to deflect?
  - Often expressed in [T-m] (easy to calculate B)
  - Be careful when q≠e!!
- A very useful expression

efferson Lab

Beam

$$\frac{p[{\rm GeV/c}]}{q[e]} \approx 0.3 \, B[{\rm T}] \, \rho[{\rm m}]$$

- Another very useful expression for particle angular frequency in a constant field: cyclotron frequency
- In the nonrelativistic approximation

Jefferson Lab

$$\omega_{\text{nonrelativistic}} \approx \frac{qB}{m}$$

Revolution frequency is independent of radius or energy!

#### Lawrence and the Cyclotron

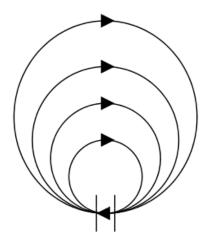

Ernest Orlando Lawrence

Jefferson Lab

 Can we repeatedly spiral and accelerate particles through the same potential gap?

Accelerating gap  $\Delta\Phi$ 

22

T. Satogata / January 2013

**USPAS Accelerator Physics** 

# **Cyclotron Frequency Again**

Recall that for a constant B field

efferson Lab

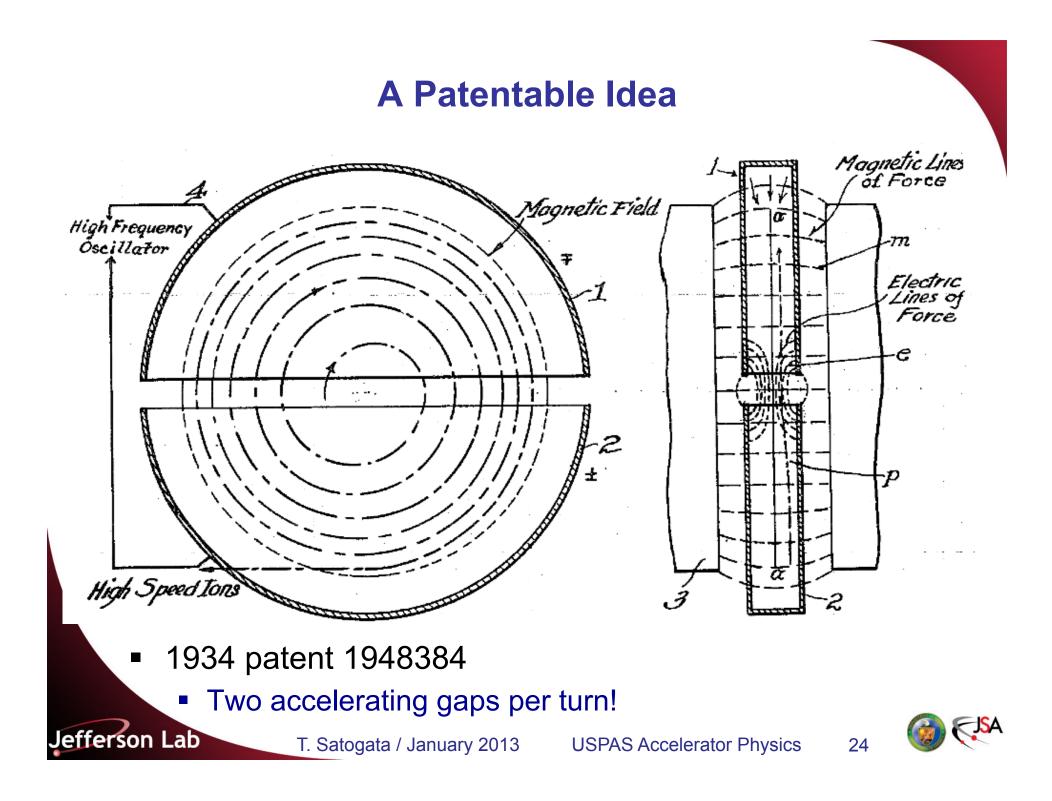

$$p = \gamma m v = q(B\rho) \quad \Rightarrow \quad \rho = \left(\frac{\gamma m}{qB}\right) v$$

- Radius/circumference of orbit scale with velocity
  - Circulation time (and frequency) are independent of v
- Apply AC electric field in the gap at frequency f<sub>rf</sub>
  - Particles accelerate until they drop out of resonance

$$\omega = \frac{v}{\rho} = \frac{qB}{\gamma m}$$
  $f_{\rm rf} = \frac{\omega}{2\pi} = \frac{qB}{2\pi\gamma m}$ 

- Note a first appearance of "bunches", not DC beam
- Works best with heavy particles (hadrons, not electrons)

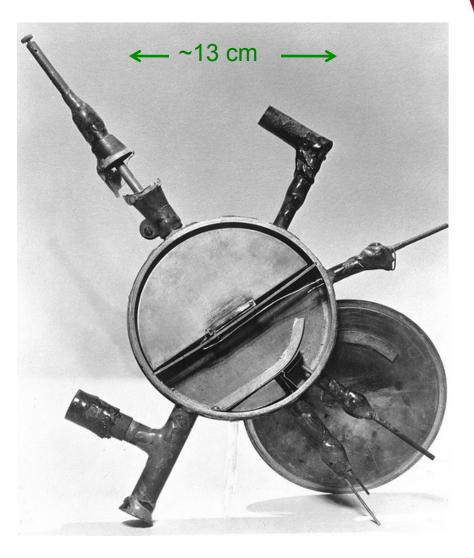

#### **All The Fundamentals of an Accelerator**

- Large static magnetic fields for guiding (~1T)
  - But no vertical focusing
- HV RF electric fields for accelerating
  - (No phase focusing)
  - (Precise f control)
- p/H source, injection, extraction, vacuum
- 13 cm: 80 keV
- 28 cm: 1 MeV

Jefferson Lab

- 69 cm: ~5 MeV
  - ... 223 cm: ~55 MeV

(Berkeley) T. Satogata / January 2013

#### Livingston, Lawrence, 27"/69 cm Cyclotron

Jefferson Lab

## **The Joy of Physics**

- Describing the events of January 9, 1932, Livingston is quoted saying:
  - "I recall the day when *I had adjusted the oscillator to a new high frequency*, and, with *Lawrence looking over my shoulder*, tuned the magnet through resonance. As the galvanometer spot swung across the scale, indicating that protons of 1-MeV energy were reaching the collector, *Lawrence literally danced around the room with glee*. The news quickly spread through the Berkeley laboratory, and we were busy all that day demonstrating million-volt protons to eager viewers."

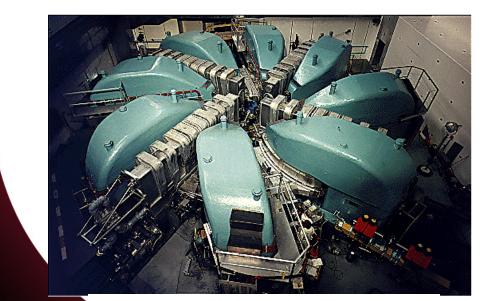

APS Physics History, Ernest Lawrence and M. Stanley Livingston

efferson Lab

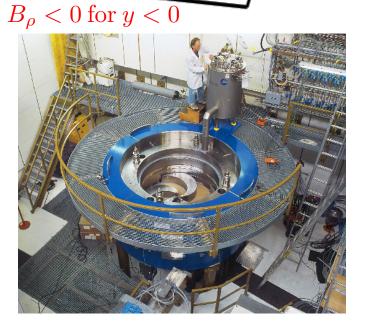

#### **Modern Isochronous Cyclotrons**

- Higher bending field at higher energies
  - But also introduces vertical defocusing
  - Use bending magnet "edge focusing"  $B_{\rho} > 0$  for y > 0(Tuesday magnet lecture)

590 MeV PSI Isochronous Cyclotron (1974) Jefferson Lab

T. Satogata / January 2013

 $f_{\rm rf} = \frac{qB(\mu)}{2\pi\gamma(\rho)}$ 

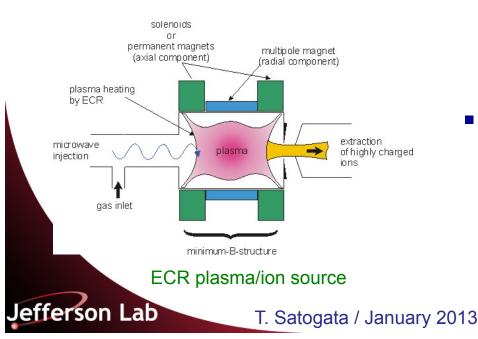

250 MeV PSI Isochronous Cyclotron (2004) **USPAS Accelerator Physics** 28

# **Electrons, Magnetrons, ECRs**

#### Radar/microwave magnetron

- Cyclotrons aren't good for accelerating electrons
  - Very quickly relativistic!
- But narrow-band response has advantages and uses
  - Magnetrons
    - generate resonant high-power microwaves from circulating electron current
  - ECRs
    - generate high-intensity ion beams and plasmas by resonantly stripping electrons with microwaves

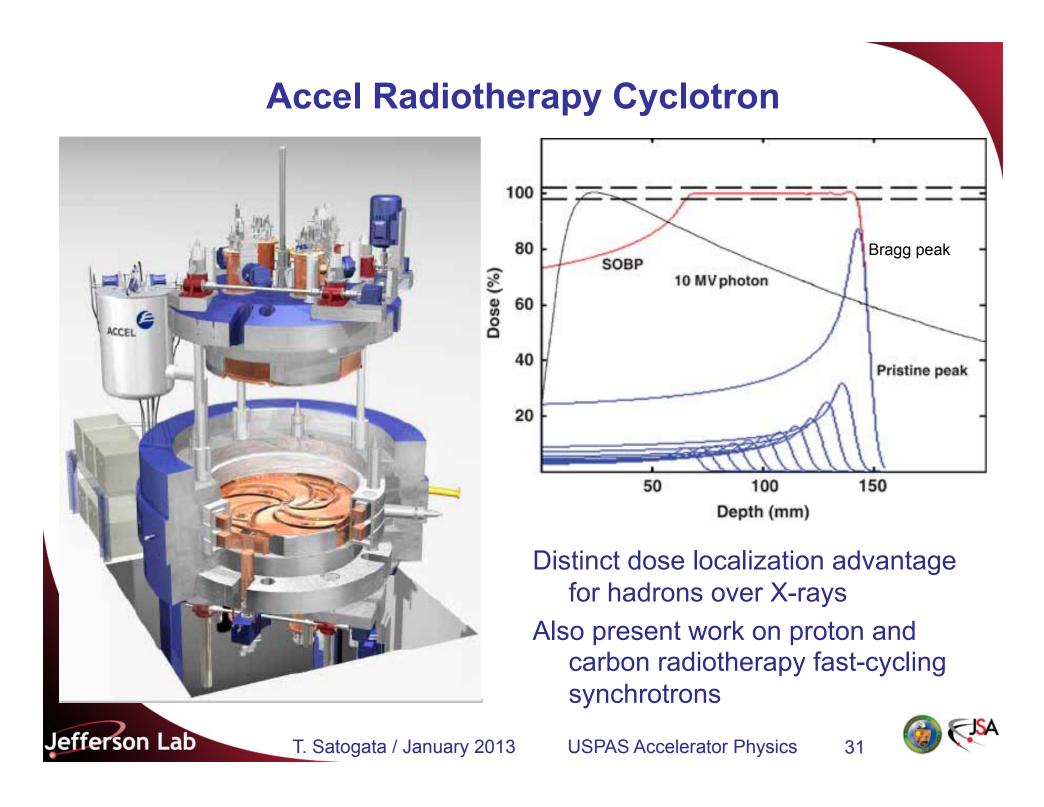

# **Cyclotrons Today**

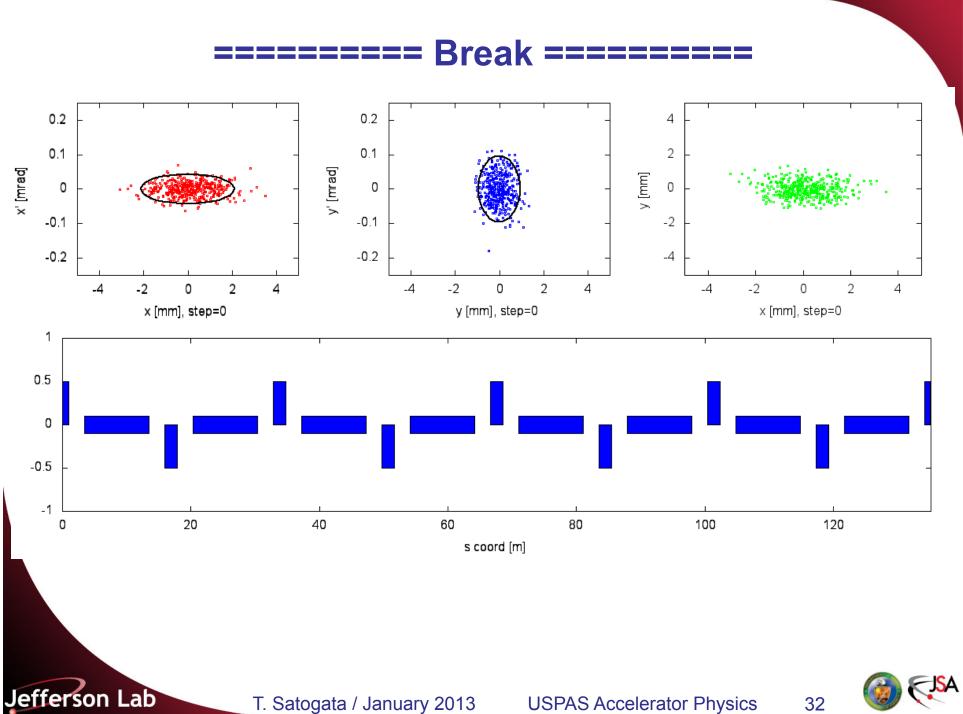

Cyclotrons continue to evolve

efferson Lab

- Many contemporary developments
  - Superconducting cyclotrons
  - Synchrocyclotrons (FM modulated RF)
  - Isochronous/Alternating Vertical Focusing (AVF)
  - FFAGs (Fixed Field Alternating Gradient)
- Versatile with many applications even below ~500 MeV
  - High power (>1MW) neutron production
  - Reliable (medical isotope production, ion radiotherapy)
  - Power+reliability: ~5 MW p beam for ADSR (accelerator driven subcritical reactors, e.g. Thorium reactors)

# (Brief) Survey of Accelerator Concepts

- Producing accelerating gaps and fields (DC/AC)
- Microtrons and their descendants
- Betatrons (and betatron motion)
- Synchrotrons
  - Fixed Target Experiments
  - Colliders and Luminosity (Livingston Plots)
  - Light Sources (FELs, Compton Sources)
- Others include

lefferson Lab

- Medical Applications (radiotherapy, isotope production)
- Spallation Sources (SNS, ESS)
- Power Production (ADSR)

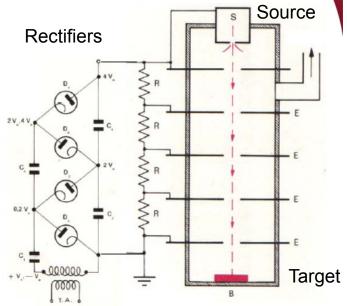

#### **DC Accelerating Gaps: Cockcroft-Walton**

- Accelerates ions through successive electrostatic voltages
  - First to get protons to >MeV
  - Continuous HV applied through intermediate electrodes
  - Rectifier-multipliers (voltage dividers)
  - Limited by HV sparking/breakdown
  - FNAL still uses a 750 kV C-W
- Also example of early ion source
  - H gas ionized with HV current

Jefferson Lab

Provides high current DC beam

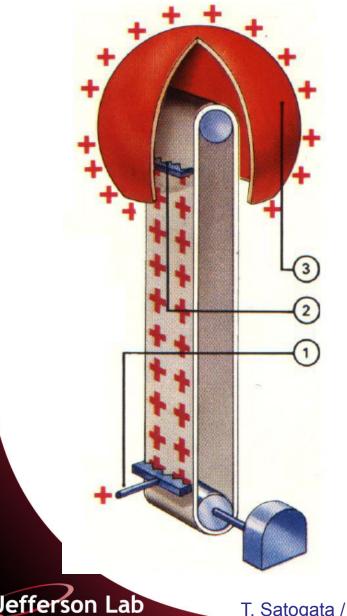

34

USPAS Accelerator Physics

## DC Accelerating Gaps: Van de Graaff

- How to increase voltage?
  - R.J. Van de Graaff: charge transport
  - Electrode (1) sprays HV charge onto insulated belt
  - Carried up to spherical Faraday cage
  - Removed by second electrode and distributed over sphere
- Limited by discharge breakdown
  - ~2MV in air
  - Up to 20+ MV in SF<sub>6</sub>!
  - Ancestors of Pelletrons (chains)/ Laddertrons (stripes)

#### Van de Graaff Popularity

36

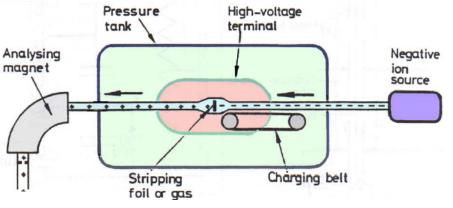

Jefferson Lab

## DC Accelerating Gaps: Tandem Van de Graaff

- Reverse ion charge state in middle of Van de Graaff allows over twice the energy gain
  - Source is at ground

Jefferson Lab

- This only works for negative ions
- However, stripping need not be symmetric
  - Second stage accelerates more efficiently
- BNL: two Tandems (1970, 14 MV, 24m)
  - $Au^{-1}$  to  $Au^{+10}/Au^{+11}/Au^{+12}$  to  $Au^{+32}$  for RHIC
  - About a total of 0.85 MeV/nucleon total energy

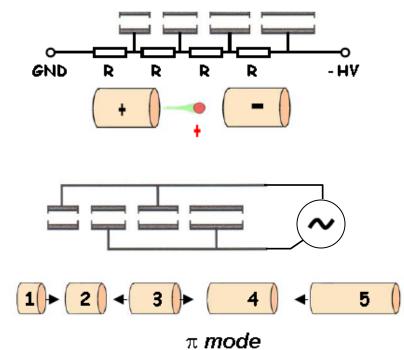

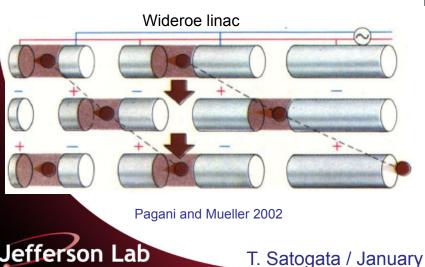

37

USPAS Accelerator Physics

#### From Electrostatic to RF Acceleration

- Cockcroft-Waltons and Van de Graaffs have DC voltages, E fields
- What about putting on AC voltage?
  - Attach consecutive electrodes to opposite polarities of ACV generator
  - Electric fields between successive electrodes vary sinusoidally
  - Consecutive electrodes are 180 degrees out of phase ( $\pi$  mode)
  - At the right drive frequency, particles are accelerated in each gap
    - While polarity change occurs, particles are shielded in drift tubes
    - To stay in phase with the RF, drift tube length or RF frequency must increase at higher energies

## **Resonant Linac Structures**

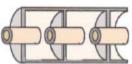

- Wideroe linac:  $\pi$  mode  $\square$   $\square$   $\square$   $\square$
- Alvarez linac: 2π mode (
- Need to minimize excess RF power (heating)
  - Make drift tubes/gaps resonant to RF frequency
  - In 2π mode, currents in walls separating two subsequent cavities cancel; tubes are passive
  - We'll cover RF and longitudinal motion next week...

Jefferson Lab

 $\pi$  mode

 $2\pi$  mode

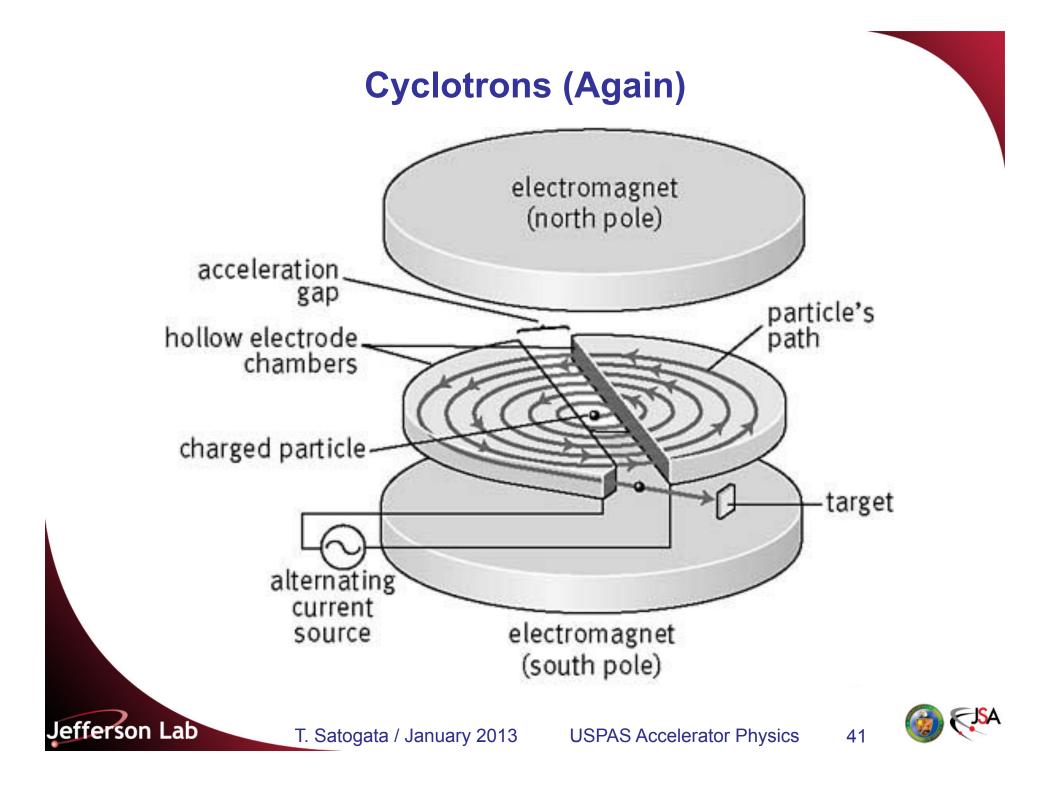

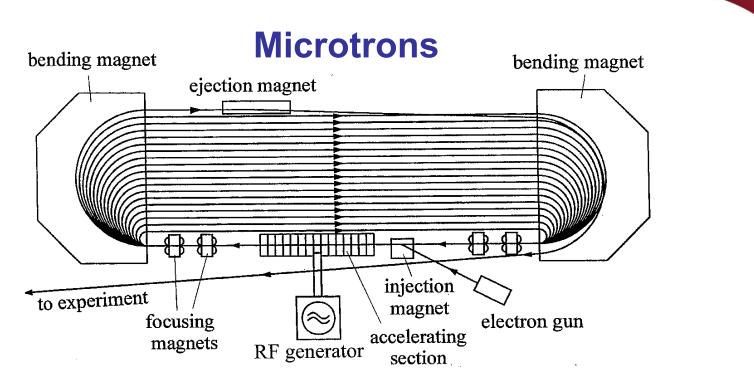

## **Advanced Acceleration Methods**

- How far do accelerating gradients go?
  - Superconducting RF acceleration: ~40 MV/m
  - CLIC: ~100 MV/m
    - Two-beam accelerator: drive beam couples to main beam
  - Dielectric wall acceleration: ~100 MV/m
    - Induction accelerator, very high gradient insulators
  - Dielectric wakefield acceleration: ~GV/m
  - Laser plasma acceleration: ~30 GV/m
    - electrons to 1 GeV in 3.3 cm
    - particles ride in wake of plasma charge separation wave

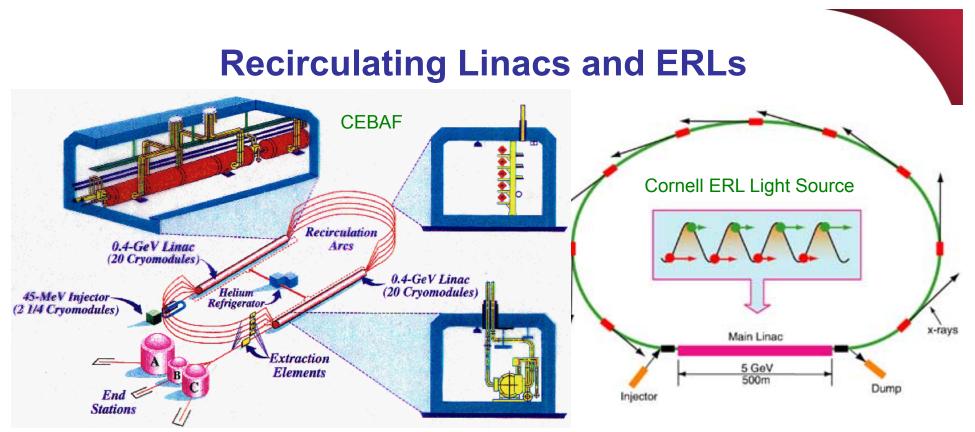

- What about electrons? Microtrons are like cyclotrons
  - but each revolution electrons "slip" by integer # of RF cycles
  - Trades off large # of revs for minimal RF generation cost
  - Bends must have large momentum aperture

Jefferson Lab

- Used for medical applications today (20 MeV, 1 big magnet)
- Mainz MAMI: 855 MeV, used for nuclear physics

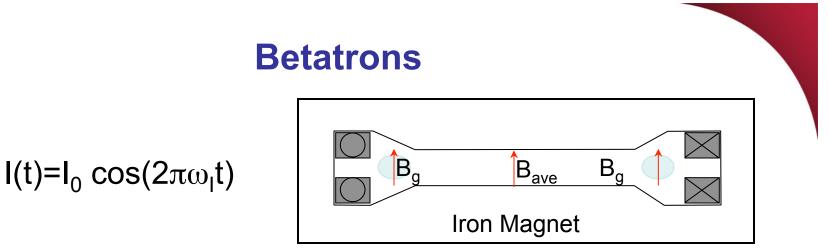

- Recirculating linacs have separate arcs, longer linacs
  - CEBAF: 4->6->12 GeV polarized electrons, 2 SRF linacs
  - Higher energy at cost of more linac, separated bends
- Energy recovery linacs recirculate exactly out of phase
  - Raise energy efficiency of linac, less beam power to dump
  - Requires high-Q SRF to recapture energy efficiently

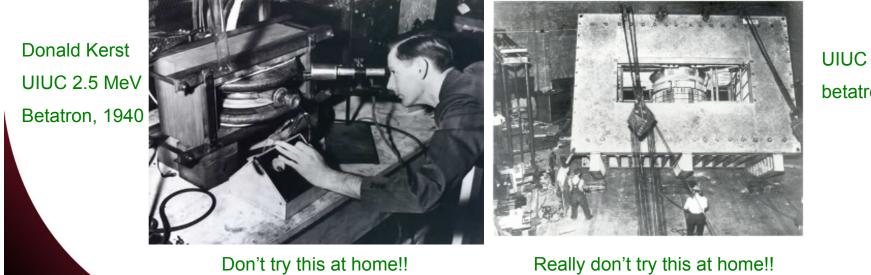

Jefferson Lab

- Apply Faraday's law with time-varying current in coils
- Beam sees time-varying electric field accelerate half the time!
- Early proofs of stability: focusing and betatron motion

UIUC 312 MeV betatron, 1949

T. Satogata / January 2013

Jefferson Lab

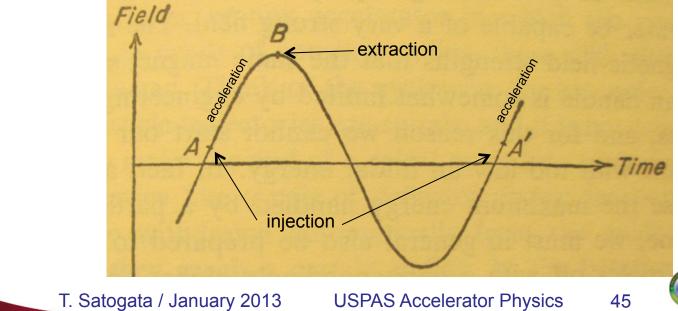

USPAS Accelerator Physics

ΔΔ

# Betatrons

Jefferson Lab

Wilson and Littauer: "Accelerators, Machines of Nuclear Physics"

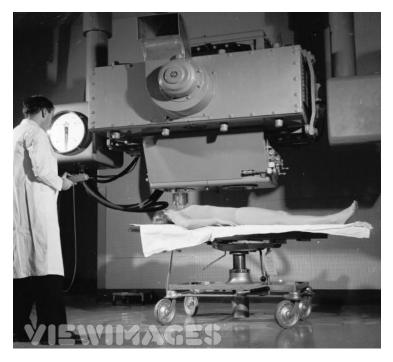

## **Betatrons**

- Betatrons produced electrons up to 300+ MeV
  - Early materials and medical research
  - Also produced medical hard X-rays and gamma rays
- Betatrons have their challenges
  - Linear aperture scaling
  - Large stored energy/impedance
  - Synchrotron radiation losses
  - Quarter duty cycle

lefferson Lab

Ramping magnetic field quality

This will only hurt a bit...

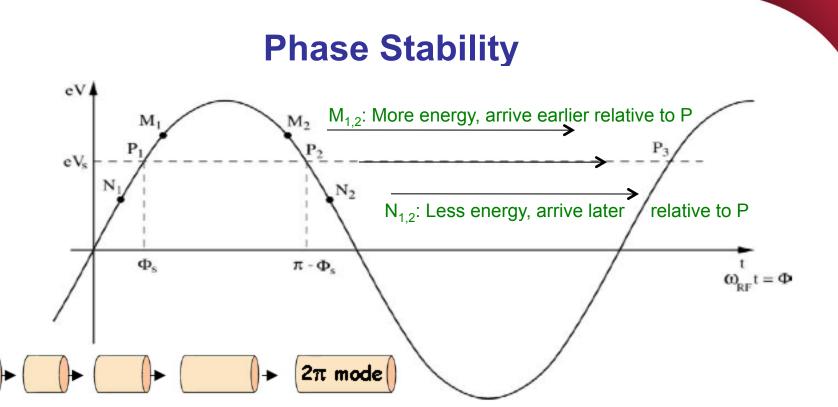

46

- More on betatrons/weak focusing this afternoon

T. Satogata / January 2013

USPAS Accelerator Physics

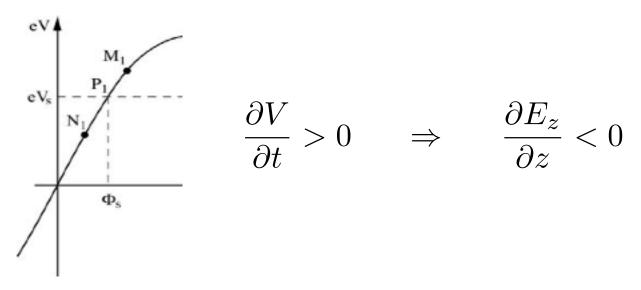

- Consider a series of accelerating gaps (or a ring with one gap)
  - By design there is a synchronous phase  $\Phi_s$  that gains just enough energy to hit phase  $\Phi_s$  in the next gap
  - P<sub>1,2</sub> are fixed points: they "ride the wave" exactly in phase
- If increased energy means increased velocity ("below transition")
  - M<sub>1</sub>,N<sub>1</sub> will move towards P<sub>1</sub> (local stability) => phase stability
  - M<sub>2</sub>, N<sub>2</sub> will move away from P<sub>2</sub> (local instability)

Jefferson Lab

## Phase Stability Implies Transverse Instability

 For phase stability, longitudinal electric field must have a negative gradient. But then (source-free) Maxwell says

$$\vec{\nabla} \cdot \vec{E} = 0 \quad \Rightarrow \quad \frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y} + \frac{\partial E_z}{\partial z} = 0 \quad \Rightarrow \quad \frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y} > 0$$

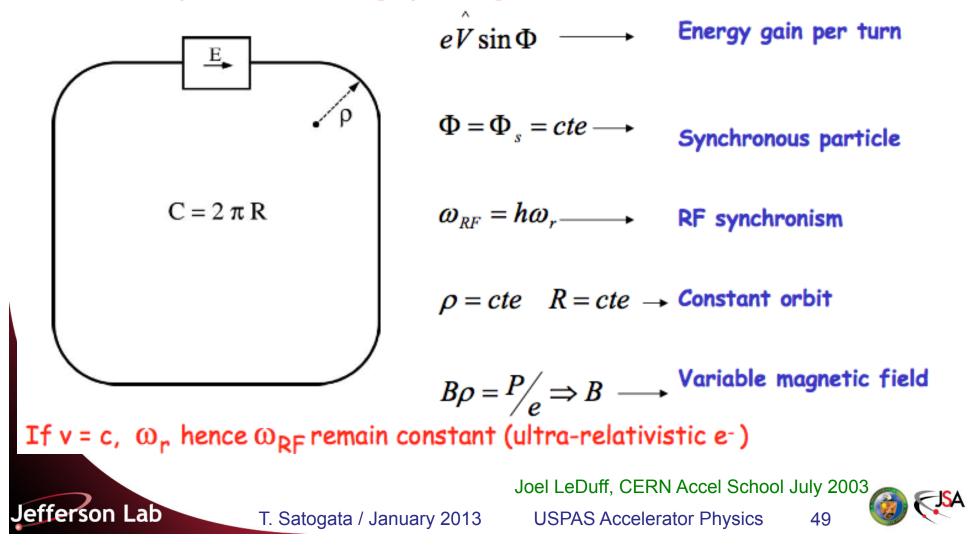

There must be some transverse defocusing/diverging force! Any accelerator with RF phase stability (longitudinal focusing) needs transverse focusing! (solenoids, quads...)

Jefferson Lab

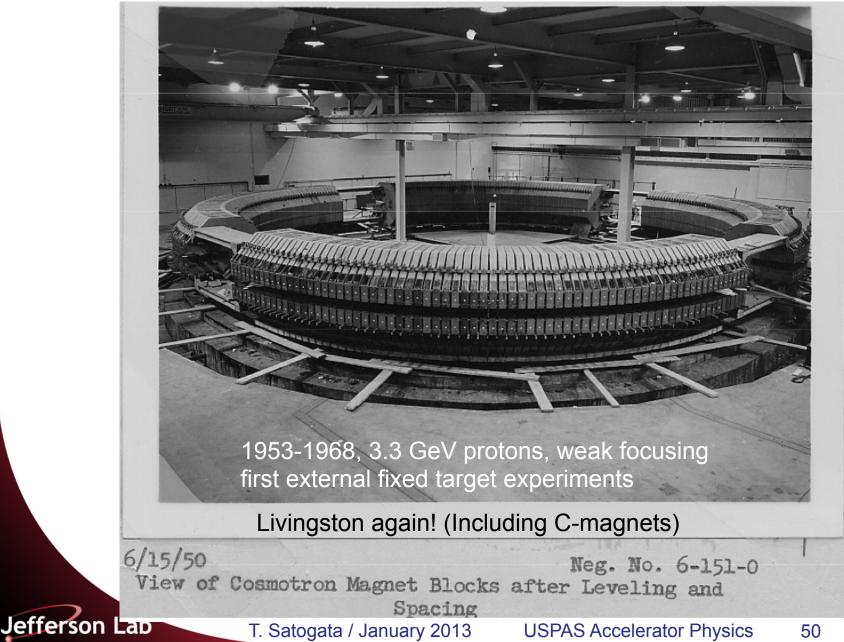

## **The Synchrotron**

The synchrotron is a synchronous accelerator since there is a synchronous RF phase for which the energy gain fits the increase of the magnetic field at each turn. That implies the following operating conditions:

#### **BNL Cosmotron**

National Academy of Sciences, Biographical Memoir of M. Stanley Livingston by Ernest D. Courant

#### **LBL Bevatron**

- Last and largest weak-focusing proton synchrotron

Jefferson Lab

- 1954, Beam aperture about 4' square!, beam energy to 6.2 GeV
- Discovered antiproton 1955, 1959 Nobel for Segre/Chamberlain (Became Bevelac, decommissioned 1993, demolished recently)

# **Fixed Target Experiments**

- Why did the Bevatron need 6.2 GeV protons?
  - Antiprotons are "only" 930 MeV/c<sup>2</sup> (times 2...)
  - Bevatron used Cu target, p+n->p+n+p+pbar
  - Mandelstam variables give:

lefferson Lab

$$\frac{E_{\rm cm}^2}{c^2} = 2\left(\frac{E_1E_2}{c^2} + p_{\rm z1}p_{\rm z2}\right) + (m_{01}c)^2 + (m_{02}c)^2$$
  
• Fixed Target experiment  

$$(4m_{\rm p0}c)^2 < \frac{E_{\rm cm}^2}{c^2} = 2\frac{E_1m_{\rm p0}}{c^2} + 2(m_{\rm p0}c)^2 \implies E_1 > 7m_{\rm p0}c^2$$
  

$$E_{\rm cm} = \sqrt{2E_1(m_{02}c^2)}$$

- Available CM energy scales with root of beam energy
  - Main issue: forward momentum conservation steals energy

## **Two Serious Problems**

- These machines were getting way too big
  - Bevatron magnet was 10,000 tons
  - Apertures scale linearly with machine size, energy

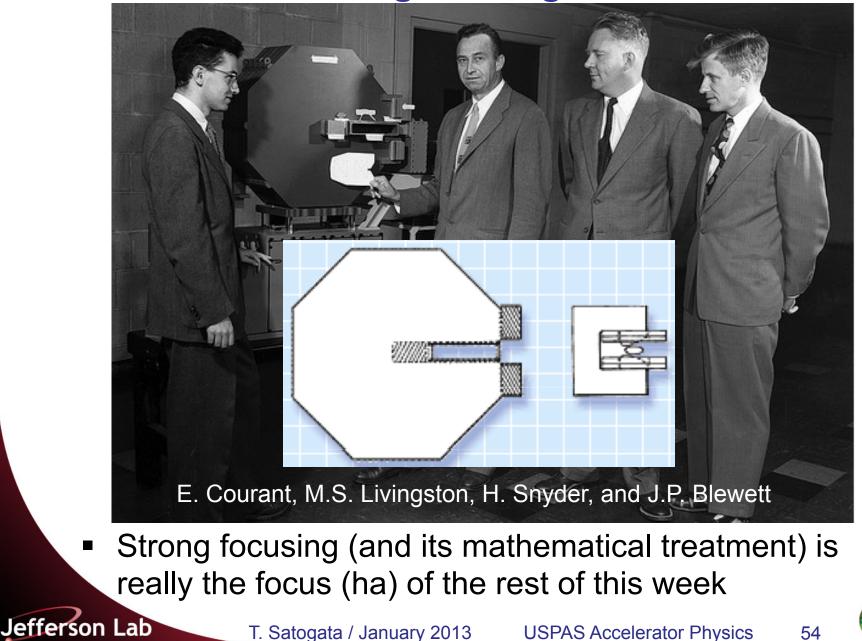

(Length/circumference scales linearly with energy at fixed field strength too...)

- Fixed target energy scaling is painful
  - Available CM energy only scales with  $\sqrt{E_{beam}}$
- Accelerator size grew with the square of desired CM energy
  - Something had to be done!!!

efferson Lab

Strong Focusing (1952) and Colliders (1958-62ish) to the rescue!!!

#### Livingston \*Again\*?

## **Collider Experiments**

- What if the Bevatron was a collider?
  - Antiprotons are "only" 930 MeV/c<sup>2</sup> (times 2...)
  - Two-body system (Mandelstam variables) gives (again):

$$\frac{E_{\rm cm}^2}{c^2} = 2\left(\frac{E_1E_2}{c^2}\right) + p_{\rm z1}p_{\rm z2} + (m_{01}c)^2 + (m_{02}c)^2$$

Case 2: Collider

efferson Lab

$$E_1 \gg m_{01}c^2$$
  $E_2 \gg m_{02}c^2$   
 $E_{\rm cm} = 2\sqrt{E_1E_2} = 2E$  if  $E_1 = E_2$ 

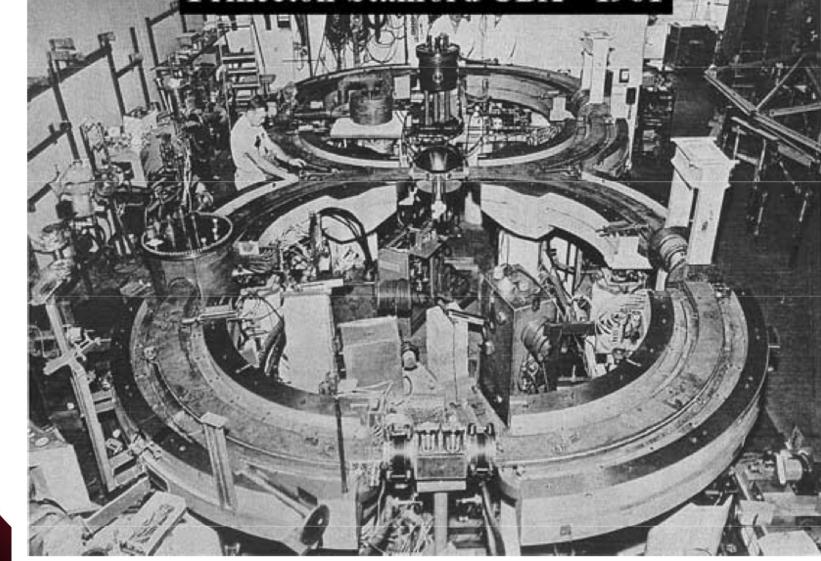

- Linear scaling with beam energy!
- For Bevacollidatron, e- + e+ -> p+pbar is possible!

(Although the cross section is probably pretty small)

## **First Electron Collider**

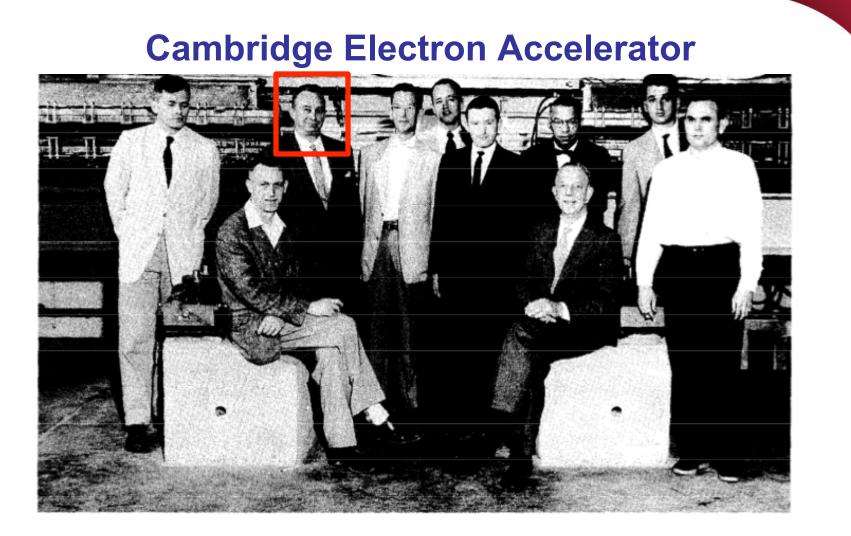

## Princeton-Stanford CBX - 1961

T. Satogata / January 2013

THE CEA TEAM, 1959. The group that led the Cambridge Electron Accelerator (CEA) in Cambridge, Massachusetts. The machine was later converted for colliding beam experiments, testing the technique of 'low-beta' that proved so important in storage rings. Sected from left: Thomas Collins and David Jacobus. Standing from left: Fred Barrington CEA Director Stanley Livinston, Robert Cummings, Lee Young, John Rees, William Jones, Janez Dekkra, and Kenneth Robinson (deceased).

# Luminosity

 Luminosity L is a measure of how many interactions of cross section σ can be created per unit time

$$L\sigma = \frac{dN}{dt}$$
  $N = \sigma \int L \, dt = \sigma L_{\text{int}}$ 

- L<sub>int</sub> is integrated luminosity, an important factor of production for colliders
- [L]= $cm^{-2} s^{-1}$ , [L<sub>int</sub>]= $cm^{-2}$  (1 ba=10<sup>-24</sup> cm; 1 pb<sup>-1</sup>=10<sup>36</sup> cm<sup>-2</sup>)
- For equal-sized head-on Gaussian beams in a collider

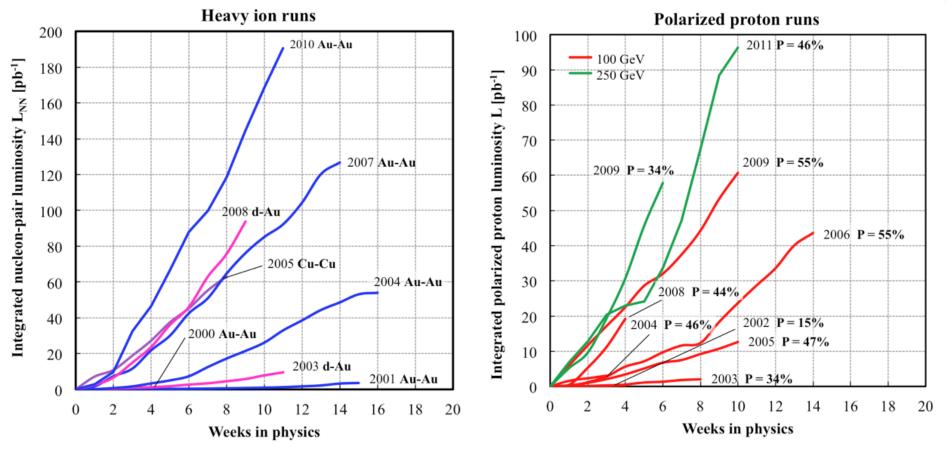

$$L = \frac{f_{\rm rev} \ h \ N_1 \ N_2}{4\pi\sigma_x\sigma_y}$$

- $\sigma_{x,y}$  are rms beam sizes, h is number of bunches
  - Colliding 100  $\mu m$  7.5e9p bunches at 100 kHz for 1 year gives about 1  $pb^{\text{-1}}$  of integrated luminosity
  - See Appendix D of the text for more details about luminosity

efferson Lab

# **Evolution of RHIC Collider Luminosities**

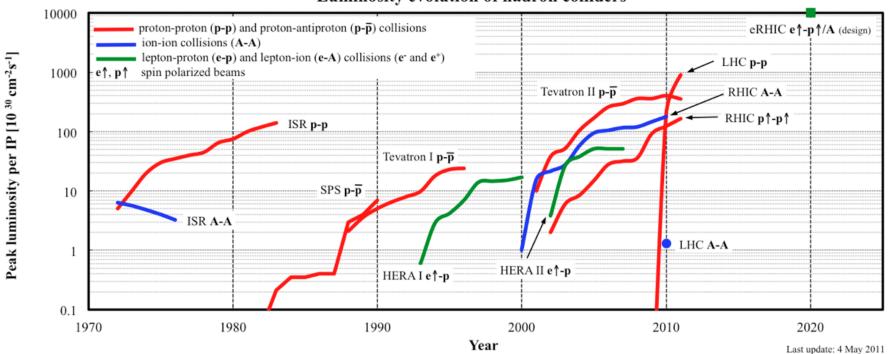

Note: The nucleon-pair luminosity is defined as  $L_{NN} = A_1 A_2 L$ , where L is the luminosity, and  $A_1$  and  $A_2$  are the number of nucleons of the ions in the two beam respectively.

W. Fischer, http://www.rhichome.bnl.gov/RHIC/Runs

Jefferson Lab

# **Evolution of Hadron Collider Luminosities**

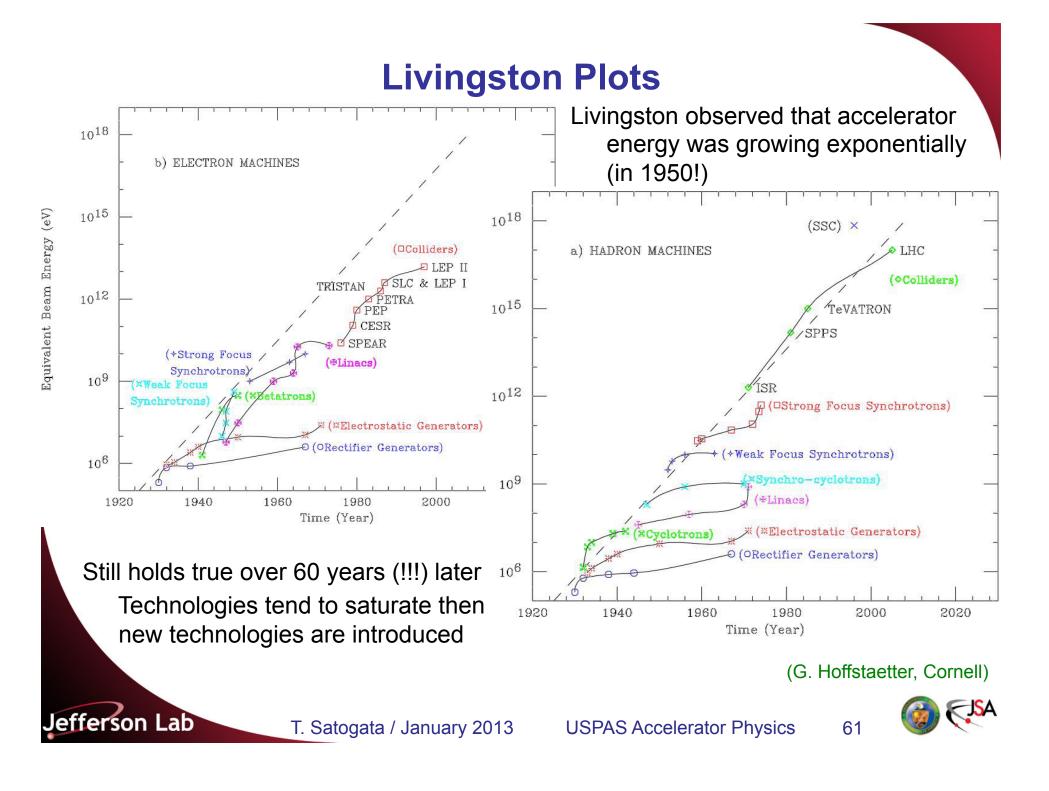

Luminosity evolution of hadron colliders

Note: For ion collisions the nucleon-pair luminosity is shown. The nucleon-pair luminosity is defined as  $L_{NN} = A_1A_2L$ , where L is the luminosity, and  $A_1$  and  $A_2$  are the number of nucleons of the ions in the two beam respectively. The highest energies for the machines are: ISR 31 GeV, SPS 315 GeV, Tevatron 980 GeV, HERA 920 GeV (p) 27.5 GeV (e), RHIC 250 GeV, LHC 3.5 TeV.

## **Cover Of The Rolling Stone**

- Accelerators make the cover of June 2011
   Physics Today
  - Micromachining example from synchrotron light
- Industrial applications

Jefferson Lab

 Plenty of applications and interest across the world

Accelerators in the industrial toolbox

## **Lorentz Lie Group Generators I**

 Lorentz transformations can be described by a Lie group where a general Lorentz transformation is

$$A = e^L \qquad \det A = e^{\operatorname{Tr} L} = +1$$

where L is 4x4, real, and traceless. With metric g, the matrix gL is also antisymmetric, so L has the general six-parameter form

$$L = \begin{pmatrix} 0 & L_{01} & L_{02} & L_{03} \\ L_{01} & 0 & L_{12} & L_{13} \\ L_{02} & -L_{12} & 0 & L_{23} \\ L_{03} & -L_{13} & -L_{23} & 0 \end{pmatrix}$$

Deep and profound connection to EM tensor  $\mathsf{F}^{\alpha\beta}$

Jefferson Lab

## **Lorentz Lie Group Generators III**

- $(S_{1,2,3})^2$  and  $(K_{1,2,3})^2$  are diagonal.
- $(\epsilon \cdot S)^3 = -\epsilon \cdot S$  and  $(\epsilon \cdot K)^3 = \epsilon \cdot K$  for any unit 3-vector  $\epsilon$
- Nice commutation relations:

efferson Lab

 $[S_i, S_j] = \epsilon_{ijk} S_k \quad [S_i, K_j] = \epsilon_{ijk} K_k \quad [K_i, K_j] = -\epsilon_{ijk} S_k$ 

• We can then write the Lorentz transformation in terms of two three-vectors (6 parameters)  $\omega, \zeta$  as

$$L = -\omega \cdot S - \zeta \cdot K \qquad A = e^{-\omega \cdot S - \zeta \cdot K}$$

- Electric fields correspond to boosts
- Magnetic fields correspond to rotations
- Deep beauty in Poincare, Lorentz, Einstein connections
